

What is MVC?

MVC is an architectural pattern that separates an application into three main logical components: **Model**, **View**, and **Controller**.

Each of these components are built to handle specific development aspects of an application.

The design logic is to separate the "logic processing" and the "data presentation" parts, clearly distinguish the functions of each component, which makes it easier to **extend**, improve **usability**, and each team member can do development **without affecting** each other.

Model View Controller(MVC)

Model

The model is responsible for communicating with the database (such as: accessing data), it is not dependent on View and Controller, that is, Model does not care how the data is displayed and operated.

View

View is responsible for managing the display of data, without any program logic. Corresponding to web development, it is the HTML template.

Controller

Controller is responsible for the **interaction** with client, and is the **bridge** between Model and View. Controller will get data from Model, and pass the data to View to generate HTML template, and return the HTML page with data to client.
